rRNA gene clusters, when active, give rise to the nucleolus.
They are thus known as nucleolus organizer regions (NORs)

one 45S rRNA gene

Back in 1995-'96:

Use of RFLPs larger than 100 kbp to map the position and internal organization of the nucleolus organizer region on chromosome 2 in *Arabidopsis thaliana*

- *A. thaliana* has two NORs
- The NORs mapped to the very tops of chromosomes 2 and 4. We named them *NOR2* and *NOR4*.
- Telomere repeats cap the most distal rRNA genes of both NORs. We named the telomere loci *TEL2N* and *TEL4N*
- We estimated that the NORs consisted of ~375 rRNA genes and were each ~3.7-4 Mbp long (in accessions Ler-0 and Col-0).

A. thaliana rRNA genes are nearly identical in 'sequence complexity', but there is variation

Variation in the accession (strain) Col-0

A. Visual assembly by dot-plot puzzle fitting

Nastva McKinlav

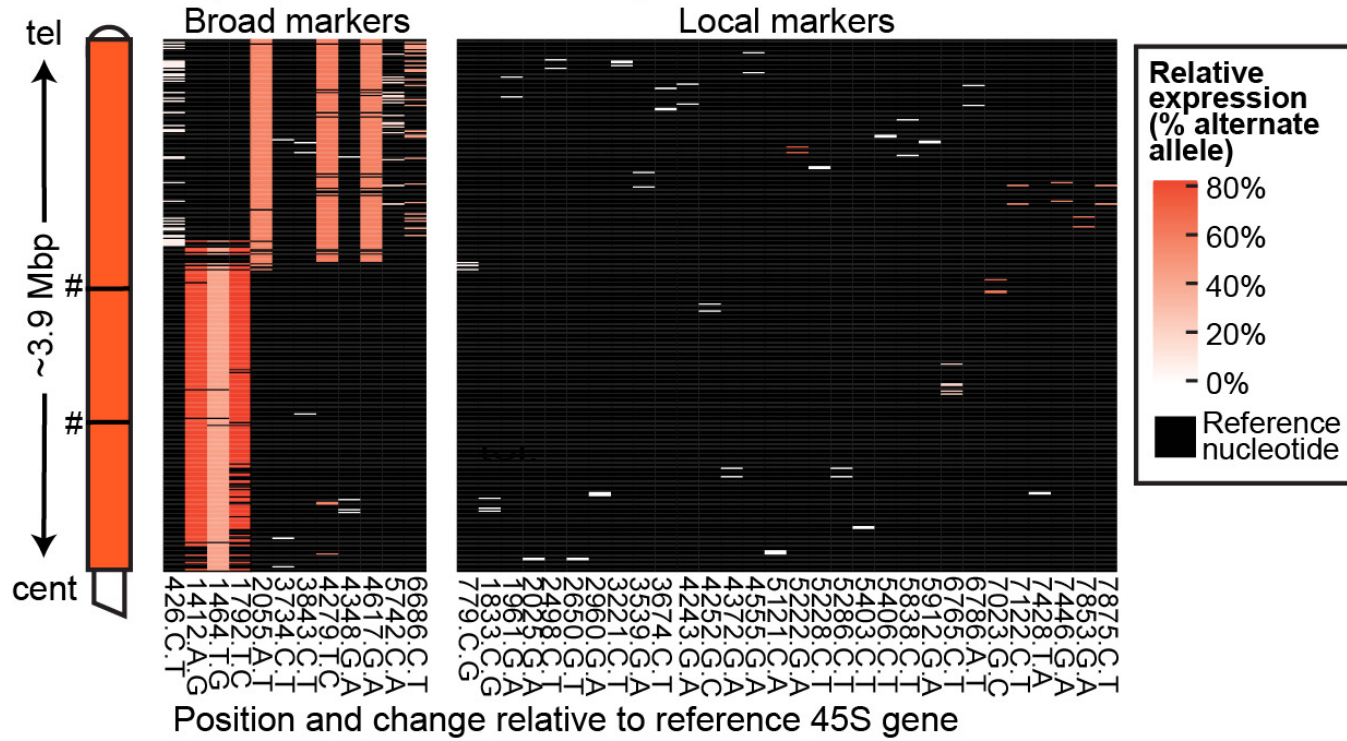

NOR2: ~5.5 Mbp; composed of 47 rRNA gene subtypes

NOR4: ~3.9 Mbp; composed of 27 rRNA gene subtypes

A. RNA-seq expression of *NOR4*-specific SNPs

B. RNA-seq expression of *NOR2*-specific SNPs

Cytosine methylation and rRNA gene expression

NOR4

NOR2

- The NOR sequences fill the last remaining gaps in the *A. thaliana Col-0* reference genome, adding ~ 9.4 million basepairs of sequence and positional information for ~900 rRNA genes of 74 subtypes
- The dominant NOR, *NOR4* is not uniformly active: a central, ~2 Mbp region accounts for most rRNA synthesis (during vegetative growth).
- *NOR2* is mostly, but not entirely, silenced. This involves histone deacetylation and cytosine methylation.
- Enables the first whole-NOR analyses of selective rRNA gene activity, the epigenetic phenomenon known as nucleolar dominance
